

Marginal bone maintenance and Astra Tech Implant System™

The design features of a dental implant system are crucial to the long-term marginal bone stability. Optimal biomechanical bone stimulation from the implant and the stable seal of the implant-abutment interface will help maintaining the marginal bone, and thereby the long-term function and esthetics of the implant treatment.

The peer-reviewed published scientific documentation on the maintenance of the marginal bone supporting Astra Tech implants is extensive. Several thousands of Astra Tech implants have been carefully evaluated by radiographs in clinical trials with a follow-up period of up to 12 years.

Studies reporting on the frequency distribution of marginal bone level changes in periodontally compromised patients, show that between 64-88% of the implants had ≤ 1.5 mm change after 3-10 years¹⁻⁴.

From studies presenting mean values of marginal bone level changes, it can be concluded that very small bone level changes occur around Astra Tech implants during the first year in function, around 0.3 mm. On average, bone levels at 5 years follow-up are maintained at 0.3 mm. Figures from two prospective studies (10⁵ and 12⁶ years) reports bone level changes of on average 0.5 mm. Thus, the Astra Tech literature shows remarkably well maintained marginal bone levels in the long-term perspective.

The table below shows published articles reporting from a minimum of 10 patients on radiographically measured mean marginal bone level changes adjacent to Astra Tech implants after a minimum of 1 year in function. All studies have good results in regard to the current standard for success for radiographically evaluated implant outcomes⁷⁻⁹ (i.e. less than 1 mm bone loss during the first year and less than 0.2 mm annually thereafter). Additionally, a meta analysis concluded that Astra Tech implant system perform even much better than the presently accepted success criteria¹⁰.
